Lab: Zoo

Some digital projects have more than one file associated with a project. For instance, a video game might have a character file, music file, coding file etc. Thus, many digital projects have different type of files such as art, music, coding, etc working together. Once you start working with multiple files you need to understand the basics of file management. File management is basically how the files relate to one another. In this lab we have a HTML that will be relating to separate image files for a zoo webpage.

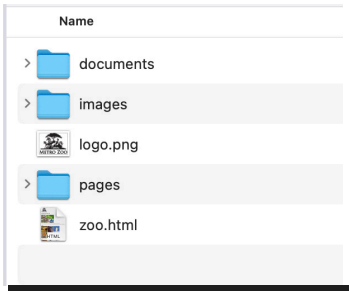

Open zoo.html

Begin by loading *zoo.html* into a code editor. You'll notice that the page is similar to other HTML documents we've worked with. Preview the page into a browser and it should look roughly like the image on the right.

Look at the File Management

Take a moment to look at the files for this lab. You'll notice there are many files including HTML and image files. This folder has folders inside of the folder as well, each folder with it's own name. If you have column-view I recommend using that.

Add the Logo

Begin by adding the image called logo.png to the *zoo.html* file. Add it BEFORE the *<h1>* in the code. Use the *<img>* tag as we've used in the past.

Save and preview and it should look something like the image on the right.

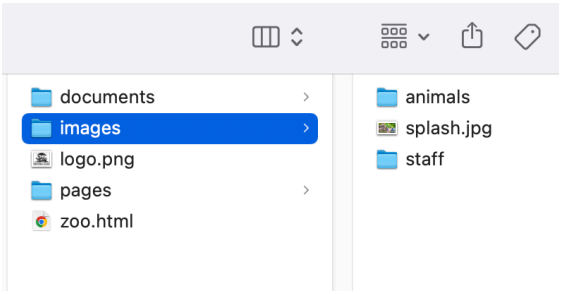

Add Splash.jpg

Next let's add the splash image of the zoo below the navigation bar. Use *<img src="splash.jpg">* to add the image to *zoo.html*.

Save and you'll notice that image does not appear when previewed. Why is that? The answer is file management. When you connect one file to another it based on the location of the file trying to connect FROM and the location of the file you are TO. For the *logo.png* the HTML and the image were in the same folder. This made it very easy for the browser to connect the two files.

For the *splash.jpg* the issue is that the HTML file and image are in different folders. This makes it a bit more complicated to connect the two files. To understand this we must understand the concept of file hierarchy. For this lab all of our files are insideo the folder called *"Zoo-Lab"*. The *"Zoo-Lab"* folder in this case our master or root folder. *zoo.html* is inside the *Zoo-Lab* folder, as is *logo.png* , a folder called *"images"* and a folder called *"pages."* This *‘"images"* folder is what is called a *subfolder*, because its a folder-within-a-folder.

In the image on the right you can see the structure, the zoo. html, logo.png and images folder are all together. If I click on the image s folder there are files inside of that subfolder. You can see that *splash.jpg* is in that subfolder.

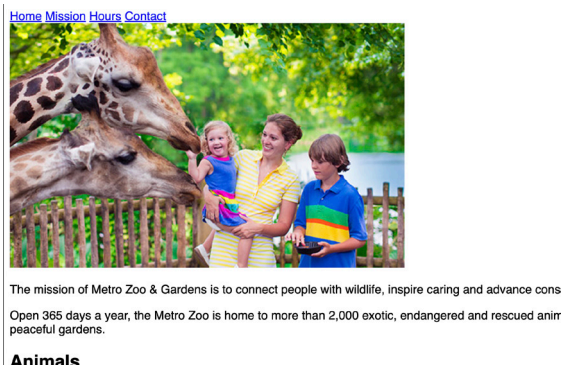

So how do we connect to an image in a subfolder? By stating the name of the subfolder in the HTML. Think of the *‘src=file”* like turn-by-turn directions from a GPS. We need to tell the browser how to get from the *zoo.html* file to the *splash.jpg* file.

Change your code to the following:

```
<img src="images/splash.jpg">
```

To break this code down, *"images"* above means ‘find a subfolder called ‘images’. The forward slash means ‘go inside that subfolder’ and the *"splash.jpg"* means look for a file with following name.

Save and preview and the splash image should appear.

Add Animal Photos

Now we want to add a few of the animal photos to this webpage to make it a bit more interesting. Let's add the *antelope.jpg* file that we have.

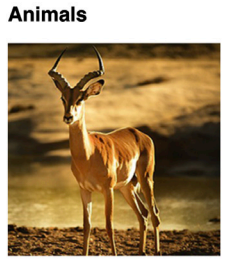

Let's add:

```
<img src="images/antelope.jpg">
```

You'll notice that the image does not appear. Why is that? We put the subfolder of 'images' right? The answer is that if you look at the file structure the animals are in an additional subfolder called 'animals'. Thus we need to call the subfolder 'images' AND the subfolder of 'animals' for the image to work. It would look like the following:

```
<img src="images/animals/antelope.jpg">
```

Save and preview and the image of the cute anteater should appear. Add at least THREE more animal images of your choice.

Add Staff Photos

Now that we've added a few animals, let's show appreciation for our staff by adding a few images of the staff. Let's add an image for Amy with *amy.jpg*.

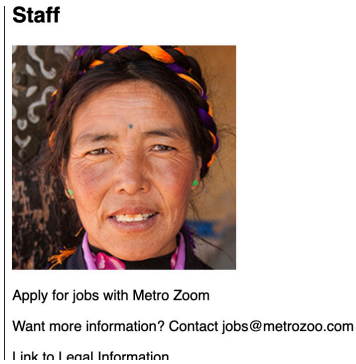

Let's add:

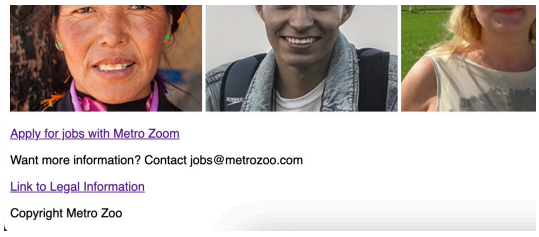

```
<img src="images/amy.jpg">
```

You'll notice the image does not appear, once again because the file management is not set up correctly. In this case we need to call the subfolder *"images"* and the subfolder of *"staff"* for the image to work.

Fix the code for Amy. Save and preview.

Now add at least two other staff member's photos to the webpage.

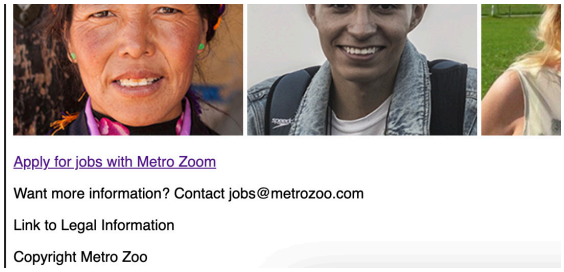

Link to Job Postings

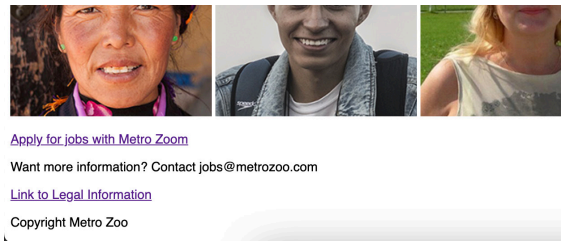

In this past we've connected an HTML page (*zoo.html*) to an image in a different folder. Now let's connect an HTML file to another HTML file that is in a different folder.

The zoo is looking to hire people and has a webpage called *jobs.html*. We want to create a hyperlink after the staff photos that links to the jobs page. So let's do that now.

Where is says 'Apply for jobs with the Metro Zoo' add a hyperlink with a title of *"link"* to *"jobs.html*." Use * *.

Save and preview and you may notice that the hyperlink does not work. Once again this occurs because the file management is not set up correctly.

The *jobs.html* is a subfolder called *"pages"*. Thus the code would look like this:

```
<a href="pages/jobs.html"> Link </a>
```

Save and preview and you'll notice the hyperlink works!

Finally, at the bottom of the page you'll notice where it says 'Link to full legal information'. Add a hyperlink that links to the HTML file *legal.html*.

Add Logo to Legal.html

Open *legal.html* into your code editor. The legal department of the zoo would like you to add the official log o of the zoo to this page.

Let's add logo.png to the top of the page. Add it after the <body> but before the text:

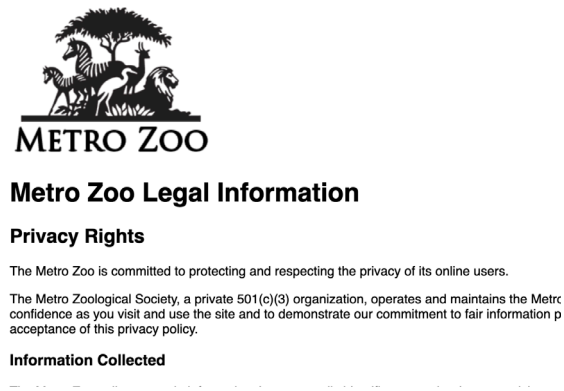

```
<img src="logo.png">
```

Save and preview you will notice that the image does not appear. Once again, this issue is due to file management. The *logo.png* file is a folder hierarchy level above *legal.html*.

So how do we reference a photo in a heirarchy level above as opposed to subfolder the answer is adding *"../"*. In file management *"../"* tells the computer that whatever folder you are in to go up one hierarchy level. If you wanted to go up two hierarchy levels you would write "*../../"* and so on.

Thus the code would look like this:

```
<img src="../logo.png">
```

Save and preview and you'll notice the image works!

Open *jobs.html* into your code editor. Add the logo to this webpage as well

Metro Zoo Jobs

Veterinarian

Looking for a skilled veterinarian willing to work with large and sometimes dangerous anim

Click to download the application form

Zoo Keeper

Submit

Save your *zoo.html* and submit your *Zoo-Lab* folder by zipping it and submitting the zip file to Canvas for grading. Make sure to rename the folder with your name on it.

Extra (not required)

Open *jobs.html* into your code editor Under the account job listing where it says 'link to application' link to *account-form.pdf*.

Under the account job listing where it says 'link to application' link to *zookeeper-form.pdf*.

Under the chef listing where it says 'link to application' link to *chef-form.pdf*.
